The survey uploaded to the preprint server [ResearchGate](#) presented data from more than 18,500 respondents from the “Control Group” project with more than 300,000 overall participants. An analysis revealed that compared to those who got jabbed, unvaccinated people reported fewer hospitalizations.

The international survey also found that the unvaccinated people from more than 175 countries were more likely to self-care to prevent and manage COVID-19 infection. They used natural products like vitamin D, vitamin C, zinc, quercetin, and drugs, such as ivermectin and hydroxychloroquine.

Many participants experienced discrimination for refusing the administration of “genetic vaccines” and struggled with mental health burdens due to the stigma in the mostly “vaccinated” society.

Over 65? Dr. Fauci Warns of a "Severe Outcome" to COVID If You Don't Do This Over the last two years, [the coronavirus](#) has made one million Americans so severely ill that they have died as a result. While that tragic outcome is a worst case scenario, there are a wide variety of ways a COVID case can pan out. Many people don't even know they're infected until they test positive because they [never develop symptoms](#), while others get sick enough to need hospitalization. The Centers for Disease Control and Prevention (CDC) has pinpointed a number of factors that could make you [more prone to severe COVID](#), including your age. According to the agency, your risk of being hospitalized or dying from the coronavirus increases as you get older. With that in mind, one of the nation's most notable health experts has just released a new warning for those over the age of 65. Read on to find out what you need to do to avoid a "severe outcome" from COVID.

The participants admitted to avoiding vaccines due to their preference for natural medicine interventions and skepticism of pharmaceutical interventions. They also voiced distrust of government information and fear of the possible adverse effects of the vaccines in the long run.

The survey was conducted from September 2021 through February 2022. During the period, participants experienced mild to moderate COVID-19 infection and were infrequently hospitalized.

A number of female participants suffered menstrual and bleeding abnormalities, prompting the researchers who analyzed the data to surmise that the issues might have been caused by spike protein exposure and shedding, as per [The Epoch Times](#).
